Day 6:

Answer the following questions:

1. C++ Program to swap 2 integer values. (Swap function, calling by address)

2. C++ Program that takes an array of integers and pass that array to a function to print array values after multiplying them to 10. (try to use "Array Notation" and "Pointer notation")

3. C++ Program have a function changes the position of the first point of a given line struct "each line have 2 points" ,then inside main displays the new coordinates along with line Length. (Pointer to struct)

   function prototype should be like:

   ```
   void change_Position(struct line *L, int newX, int newY)
   ```

4. C++ Program that asks the user for number of Lines he want "line is a struct, each line have 2 points", then displays length of each one.(Dynamic Allocation of 1D Array of objects)
